Is stylometry still able to distinguish between literary human and machine translation?

Rykowska, Aleksandra
aleksandra.rykowska@doctoral.uj.edu.pl
Jagiellonian University in Kraków, Poland

The fact that machine translation quality rises on a daily basis is beyond doubt. With an increasing number of users and training data, the pace of development of machine translators (MT) available on the market comes as no surprise. The biggest leap in translation quality could be seen around 2015 when classic statistical algorithms were replaced by neural machine translators (NMT) (Kenny, 2022). Although the resulting MT is far from perfect, with many errors (Al Sharou, Specia, 2022), as well as harmful stereotypes (Rescigno, Monti, 2023)..

The rise in popularity of MT is also resulting in an increase in MT research, especially from the perspective of error analysis (Haque, Hasanuzzaman, and Way, 2020; Carl, Toledo, Báez 2020; Freitag et al. 2021). Most of these focus on applied texts. Only a few studies on literary MT can be found. Voigt and Jurafsky (2012) studied referential cohesion and how it affects translation. Jones and Irvine (2013) translated literary excerpts and analyzed it qualitatively. Besacier and Schwartz (2015) and Toral, Wieling, and Way (2018) analyzed post-editing of French-English and Spanish-Catalan NMT. Toral and Way (2015) built a MT system tailored to Zafón and translated his novels from Spanish to Catalan. For 20% of the sentences, the MT and the HT were identical. ÓMurchú (2017) machine-translated a sci-fi novel from Scottish Gaelic to Irish but also focused on its post-editing. Taivalkoski-Shilov (2019) and Kenny and Winters (2020, 2024) tried to establish the translator's voice in MT, but mainly while comparing the differences between post-editing a MT by a translator who has previously translated the novel. Only Rybicki (2023) presented a stylometric study in which he warned that MT could possibly no longer be clearly distinguished from HT.

Rybicki's study was carried out only on a small and rather specific corpus – it included classic French novels. This proposal aims to reconduct this study on a larger corpus, consisting of a total of 1350 texts, comprising 150 titles each of contemporary novels (the earliest novels included in the corpus date from the 19th century) originally written in Italian, Spanish, Serbian, Croatian, Greek, Japanese, Danish, Dutch, Norwegian, Swedish, Czech, Hebrew, Hungarian, and German[1]. All texts are written in prose. Moreover, at least two books by a given author were included in the corpus, each of which had to be simultaneously translated into three languages: Polish, English, and French. Google Translate, DeepL and the official translator of the EU (https://webgate.ec.europa.eu/etranslation/), were used for MT.

The study aims to test whether MT is now stylistically indistinguishable from HT, thanks to the increased sample of literary items and the increased number of starting languages from which individual novels were translated. The research hypothesis is that in the case of English, the indistinguishability of MT from HT will be the strongest; the boundary between the two types of translation will be stylometrically most pronounced in Polish, which represents a heavily inflected language. In addition, its presence is strongly limited in AI training data.

The *stylo* package (Eder, Rybicki, Kestemont, 2016) for R was used for the analysis. A bootstrap consensus method using cosine delta for the most frequent words (100 to 1000 MFWs) was used. The results were visualized on a dependency network made with the Gephi program (Bastian, Heymann, Jacomy, 2009). The hypothesis was confirmed that in translations from languages other than French into languages other than English, the boundary between MT and HT is also blurred. Not all authors submit to this principle. In all languages, only the authors Zafón (surprising considering the aforementioned study (Toral and Way, 2015)), Dostoevsky, and Márquez stand out, as shown on Figure 1, Figure 2, and Figure 3.

Figure 1 Relations between HT and MT of Zafon's novels

Figure 2 Relations between HT and MT of Marquez novels

Figure 3 Relations between HT and MT of Dostoevski's novels

Intreresting there are novels written by same author that do not have any strong connections between HTs but MT connects them all (see Remarque on Figure 4).

Figure 4 Relations between Remarque's translations

Contrary to the author's assumptions, the criterion of analyticity and inflectionality of the language did not bear the expected impact on the study results –the most significant differences between HT and MT can be observed in English, whereas in Polish this boundary is blurred. This may be caused by the fact that translation engines handle inflectional sentence structures well, despite variation errors (Munkova et al., 2021). Similarly, in this case, the results of the stylometric analysis are not influenced by the presence of training data and whether the language is "well-resourced" or "low-resourced". There is no doubt that MT is becoming increasingly similar to HT stylometrically, both in the case of a translation produced by one of the largest and best-developed translation engines (Google) or while using a translator trained on official EU texts. It seems that the biggest factor in determining whether MT will be distinguishable from HT is the complexity of the individual style of the original in the case of novels originally written in a "well-resourced" language.

The study concludes that further analysis should be carried out, on even more extensive corpora. Ultimately, the author plans to analyze a corpus of more than 3000 texts, adding translations of novels into Lithuanian into the existing corpus. The planned research also aims to enrich the corpus with more texts originally written in minority languages and those unrelated to the Indo-European language family. However, the study presented here clearly demonstrates the correlation that literary MT needs to be investigated, as translation engines currently produce results that allow them to cheat stylometry and imitate human artistic language. The author plans to test new ways of distinguishing MT and HT based on the syntax of translated texts.

Notes

1. Full list of novels included in the corpus, as well as all visualized results of the study (here the author only presented a small selection of the results) can be found under the link: https://github.com/aleksandra2812/StylometryMT
