Introduction

A picture is worth a thousand words, particularly in history, where visuals complement text to deepen understanding of past events (Dussel & Priem 2017). E.g., visualizing a Roman triumph can animate ancient rituals in ways that textual descriptions alone cannot. Beyond enhancing engagement (Dehouche & Dehouche 2023), such visualizations offer valuable tools for scholarly research, enabling historians to model and interpret the spatial, performative, and political dimensions of historical phenomena more concretely. While some scholars criticize visual media in historical narratives (Depaepe & Henkens 2000), others argue that images function as semiotic systems comparable to language (Peim 2005), underscoring their analytical potential in reconstructing and contextualizing the past.

"""
You are an expert in historical imagery, specializing in ancient Roman history.
Your task is to analyze a given historical image and answer a question about it.
It is crucial that you provide only a Yes or No answer.

The question you need to answer about this image is: {question}

Please follow these steps:
  1. Carefully examine the image, paying close attention to details that might
be relevant to ancient Roman history.
  2. Consider the question in relation to what you observe in the image.
  3. Based on your expertise in ancient Roman history and the visual information
provided, determine whether the answer to the question is affirmative or negative.

Remember, you must answer ONLY with Yes or No
Do not provide any explanation or additional information beyond this single-word
response.
"""
```

Figure 1: Failed cases from DALL-E 3, SDXL, and FLUX.1-dev, with wrongly represented elements.

Recent advances in text-to-image (T2I) models (Yu et al. 2022, Rombach et al. 2022, Saharia et al. 2022, Ramesh et al. 2022, Betker et al. 2023) have improved generative quality, but aligning complex prompts with accurate visuals remains challenging. Misrepresentations, such as incorrect attire or architecture, are common (Figure 1), especially when prompts involve rare cultural or temporal references.

Manual prompt engineering is time-consuming and requires domain-specific expertise (Gal et al. 2023). For example, accurately describing a Roman general's attire or the Lupercalia festival can easily overwhelm non-experts. This paper addresses these challenges by introducing an automatic prompt refinement approach using retrieval-augmented GPT-4o (OpenAI 2024), which improves historical text-to-image generation through evidence-based alignment. By lowering the barrier to producing accurate visualizations, this method enables a wider range of scholars to incorporate visual representations into their research and teaching, thus expanding the use of AI-generated imagery as a tool for historical inquiry.

Our Contributions

1. A historical domain prompt-image dataset comprising 200 prompts and 6,000 images by five T2I models.
2. An automatic T2I alignment evaluation and assessment of evaluation consistency with three MLLMs.
3. A human evaluation of a subset.

Related Work

Prompt Engineering

Prompt engineering designs instructions to guide pre-trained models in generating outputs without modifying core parameters. T2I models typically employ (1) prompt tuning and (2) prompt optimization. Prompt tuning (Jia et al. 2022) adapts models with task-specific templates and few-shot examples, but scaling to large models becomes computationally intensive. Prompt optimization methods (e.g., *Promptist* (Hao et al. 2023)) refine user prompts to enhance image aesthetics. Building on these, our approach focuses on improving T2I alignment rather than aesthetics by leveraging an LLM for prompt refinement. We integrate domain-specific knowledge into prompts using retrieval-augmented generation (RAG) (Lewis et al. 2020), enabling historically accurate image generation.

Parameter-Efficient Fine-Tuning (PEFT) for Image Models

PEFT methods (Ding et al. 2023) adapt large-scale models for downstream tasks by updating only a subset of parameters. Techniques such as Low-Rank Adaptation (LoRA) (Hu et al. 2022) and adapter-based tuning (Houlsby et al. 2019) enable efficient customization. Originally developed for LLMs, these methods are now widely applied to T2I diffusion models (Saharia et al. 2022, Rombach et al. 2022, Hu et al. 2022, Mou et al. 2024, Sohn et al. 2023). Our work employs LoRA to fine-tune T2I models on a small dataset, balancing efficiency and performance to improve alignment in historical contexts.

Figure 2: Comparison of triumph images (3 random samples) generated by five T2I models using initial and refined prompts; main objects used for retrieval, added historical context.

Dataset Preparation

Our dataset was prepared in two steps:

1. **Prompt Generation** We used 100 manually crafted prompts from (Ströbel et al. 2024), comprising 75 depicting triumphal processions in ancient Rome and 25 centered on the *Lupercalia* festival.
2. **Image Model Fine-tuning and Image Generation** We generated 3,000 images using five models: DALL-E 3 (Betker et al. 2023), SDXL (Podell et al. 2024), fine-tuned SDXL, FLUX.1-dev,[1] and fine-tuned FLUX.1-dev.[2] Each prompt from step 1 was used to generate six images. For fine-tuning, we curated 276 caption-image pairs, of which 177 pairs are from two historical books (Gorski & Packer 2015b, Kiley 2013) on architecture, clothing, and weapons, and 99 are frames from the TV series Rome, S1E10,[3] automatically captioned with Claude 3.5 Sonnet.[4] We fine-tuned on Replicate using LoRA (Hu et al. 2022) and textual inversion (Gal et al. 2023) for SDXL, and Ostris's AI Toolkit for FLUX.1-dev. We applied three lora_scale values (0.2, 0.4, 0.6), generating two images per value for each prompt with the fine-tuned models. The complete dataset will be publicly available on GitHub.[5]

RAG with GPT-4o

The goal of this study is to enhance T2I alignment through automatic prompt refinement using RAG via OpenAI's Assistant API,[6] leveraging the Chain-of-Thought prompting strategy (Wei et al. 2022).

GPT-4o extracts historical objects from initial prompts within predefined categories and uses them as queries to retrieve contextual content from a historical domain database.[7] The retrieved content enriches the prompts, enabling better alignment with the historical objects described.

The experiment refined the 100 human-generated prompts, generating six images per refined prompt across five T2I models, yielding 3,000 images. We applied the same lora_scale settings from the initial dataset generation for fine-tuned models. Appendix A Figure 6 provides detailed instructions on the refinement process.

Evaluation

T2I alignment evaluates how well an image's visual semantics match a prompt's textual semantics (Yarom et al. 2023). We adopted two evaluation criteria from (Ströbel et al. 2024): (1)

QG-VQA using MLLMs across the full dataset and (2) a 5-point Likert scale evaluation with both MLLMs and human raters on a subset. The MLLMs used were GPT-4o, Gemini 1.5 Pro (Reid et al. 2024), and Claude 3.5 Sonnet.

Figure 3: Comparison of Lupercalia images (three random samples) from five T2I models using initial and refined prompts; main objects used for retrieval, added historical context.

QG-VQA Setup

The QG-VQA metric (Hu et al. 2023, Cho et al. 2024) involved generating questions with GPT-3.5 (Brown et al. 2020) and answering them using the MLLMs. Binary responses (1 for "Yes," 0 for "No") were averaged per image to compute a final alignment score ranging from 0 (no alignment) to 1 (perfect alignment). See Appendix A Figure 8 for the prompt.

"""
```

Table 3: MLLM 5-point Likert scale evaluation.

5-point Likert Scale Setup

We conducted a Likert scale evaluation on 150 randomly sampled prompt-image pairs, with 15 pairs per T2I model (10 from Triumph and 5 from *Lupercalia*). Human and MLLM raters assessed alignment on a scale from 1 (no match) to 5 (perfect match). Refined prompt-image pairs were evaluated alongside their initial counterparts, and Appendix A Figure 7 details the evaluation guidelines.

Results

Table 1 presents the average VQA scores for five T2I models: DALL-E 3, SDXL, fine-tuned SDXL, FLUX.1-dev, and fine-tuned FLUX.1-dev, using initial and refined prompts. Refined prompts consistently achieved higher VQA scores, particularly for DALL-E 3, FLUX.1, and fine-tuned FLUX.1, with the largest improvement observed for FLUX.1, which achieved a 0.22-point increase. Tables 2 and 3 detail the 5-point Likert scale evaluations by humans and MLLMs, respectively. Refined prompts notably improved alignment in the *Lupercalia* category for DALL-E 3, although performance varied in the Triumph category.

LoRA Fine-Tuning Enhances SDXL Performance. The results indicate that LoRA fine-tuning improves SDXL's T2I alignment across both VQA and Likert-scale evaluations. Fine-tuned SDXL consistently outperformed its base version, achieving the largest improvement in the Triumph category. As Tables 2 and 3 show, human *and* MLLM assessments favored fine-tuned SDXL, confirming the effectiveness of combining textual inversion with LoRA for modeling intricate historical concepts.

"""
```

Figure 5: VQA score distribution from three MLLMs for images generated with refined prompts using base (lighter saturation) and fine-tuned (darker saturation) SDXL.

Rating Divergences Among MLLMs. Figures 4 and 5 show notable differences in VQA scores across MLLMs. GPT-4o and Gemini exhibited similar scoring patterns, typically assigning mid-range scores (0.3–0.7), while Claude's ratings predominantly clustered in the lower range (0.0–0.3). Jensen-Shannon divergence analysis indicated high similarity between GPT-4o and Gemini's rating distributions for DALL-E 3 and SDXL, while Claude's scores diverged significantly. These findings are supported by inter-annotator agreement (IAA) results in Table 6, which highlight stronger alignment between GPT-4o and Gemini but lower overall agreement across all MLLMs.

Refined Prompts Lead to Better Object Alignment. As Figures 2 and 3 illustrate, refined prompts consistently produced images that better aligned with the described objects, especially in historically complex scenes. E.g., refined prompts improved depictions of Roman architectural details in Lupercalia, while initial prompts often failed to capture these nuances.

Evaluation Complexity. The IAA results in Table 4 reflect significant discrepancies in VQA evaluations among MLLMs, with all scores falling below the 0.67 threshold. These results highlight the inherent complexity of evaluating T2I alignment and underscore the need for more robust and interpretable metrics.

"""
```

Table 4: Krippendorff's # between MLLM raters' VQA scores.

Conclusion

This study demonstrates the potential of retrieval-augmented GPT-4o to enhance T2I alignment by refining prompts with historical context. Refined prompts improved alignment across five T2I models (Tables 3 and 4), with LoRA fine-tuning further enhancing SDXL performance. These results emphasize the importance of integrating historical specificity into prompt engineering.

Evaluation discrepancies among MLLMs (Table 6) highlight the need for more robust metrics, while GPT-4o's occasional hallucinations during refinement affect reliability. The small human evaluation dataset limits generalizability. Future work should explore re-ranking strategies and larger datasets to address these challenges.

By bridging gaps in T2I alignment, this work advances the generation of historically accurate visualizations, paving the way for deeper insights into historical events.
