Introduction

Digitized Sanskrit texts are essential for preserving cultural heritage and enabling scholarly research. However, a disconnect exists: the digitized texts are often shared on certain platforms (Martínez García / Gippert 1995, GRETIL 2000, Hellwig 2021), while the corresponding scans of printed books or manuscripts are stored separately on digital collections (Heidelberg University Library 2025, Munich DigitiZation Center 2025). This gap hinders integrated analysis, particularly for philological studies. Optical Character Recognition (OCR) technology is critical in bridging this gap by converting scanned images into machine-readable text. This study addresses two primary key challenges:

1. Building an OCR model for Vedic Sanskrit, which is unique challenges due to accent markings.
2. Aligning the texts with their corresponding images for accurate literary representation.

Existing OCR systems are fundamentally designed for Classical Sanskrit and are, in principle, incapable of recognizing the Vedic accent marks.

Method

Methodology Overview

To address these challenges, we propose a novel framework combining eScriptorium (Stokes et al. 2021) for layout recognition and manual modification with TrOCR (Li et al. 2023) for character recognition. This hybrid approach exploits the strengths of layout analysis tools and state-of-the-art OCR technologies.

Our process follows (see also Figure 1):

- Training data preparation: Creating line-by-line aligned text-image pairs.
- Model fine-tuning: Adapting TrOCR to recognize Vedic with limited training data.
- New data preparation: Using eScriptorium for identifying text regions in images, and manually modifying OCR outputs to align text with images.
- Iterative refinement: Repeating data generation and model training cycles for incremental improvement.

Iterative training and alignment between text and images for OCR improvement.

The resulting aligned outputs were first converted into ALTO format, and then more simple two-column format for fine-tuning.

Dataset

Our dataset comprises scans and aligned texts from Maitrāyaṇī Saṁhitā (MS). Transcriptions with page and line annotations by Makoto Fushimi sourced from TITUS (Martínez García / Gippert 1995) consist of approximately 1,000 pages and 10,000 lines. The images were from scans of the Schroeder edition (Schroeder1881).

Model

We utilized TrOCR, a Transformer-based architecture, known for its superior performance on character recognition tasks. The large variant of TrOCR for printed books, microsoft/trocr-large-printed was chosen to maximize baseline performance.

In preliminary experiments, we confirmed that Kraken, the OCR engine used in eScriptorium, produced unsatisfactory accuracy on our data even after fine-tuned by our small Vedic dataset. Our observation aligns with a recent discussion (Ströbel 2023), in which various OCR engines are evaluated on historical texts, and TrOCR outperforms Kraken and other models, demonstrating its adaptability and rapid improvement with limited data.

The model was fine-tuned to recognize printed Vedic in Devanagari as input and output roma-

nized text, aligning with the formatting of widely-used text repositories. Beyond transcription, the model supported the alignment process by generating a new training dataset.

Result

Our model demonstrated promising accuray in recognizeing printed Vedic, despite the small dataset. The common errors observed in the model's output include misreading of accent marks and confusion between visually similar characters, like # (*gh*) and # (*dh*). These errors are likely due to the rare accent marks in the training dataset, as well as the visual similarity of characters in fonts. Figure 2 is an example of our OCR model's output on a scanned line-by-line image of Vedic Sanskrit text.

Example of OCR output on a scanned line-by-line image of Vedic Sanskrit text.

The evaluation metrics are presented in Table 1. Character error rate (CER) and word error rate (WER) are widely used metrics for evaluating OCR performance, meaning that the lower is better. Character *n*-gram F1 score (CHRF1) is a metric combined with *n*-gram precision and recall, which is also used for OCR evaluation, meaning the higher the score, the better. These results highlight the potential of the model to handle printed Vedic texts, although there is still room for improvement to achieve higher accuracy.although there is still room for improvement to achieve higher accuracy.

Discussion

This study demonstrates the feasibility of building an OCR model for Vedic Sanskrit using a pipeline that combines eScriptorium and TrOCR. The integration of manually corrected layouts and the state-of-the-art character recognition enables effective model training, even with limited data.

Despite initial success, there is significant room for improvement.

Challenges such as text layout complexity, low-quality scans, and script-specific intricacies remain to be addressed.

Future work will focus on expanding training data and improving alignment automation. Furthermore, to enhance data accessibility and interoperability, we plan to adopt a platform such as *Tekst* (Fischer 2023) and integrate IIIF-compatible image references directly into TEI/XML, allowing unified access to both text and image data.
